

X-ray source populations in nearby galaxies

Andreas Zezas

Harvard-Smithsonian Center for Astrophysics

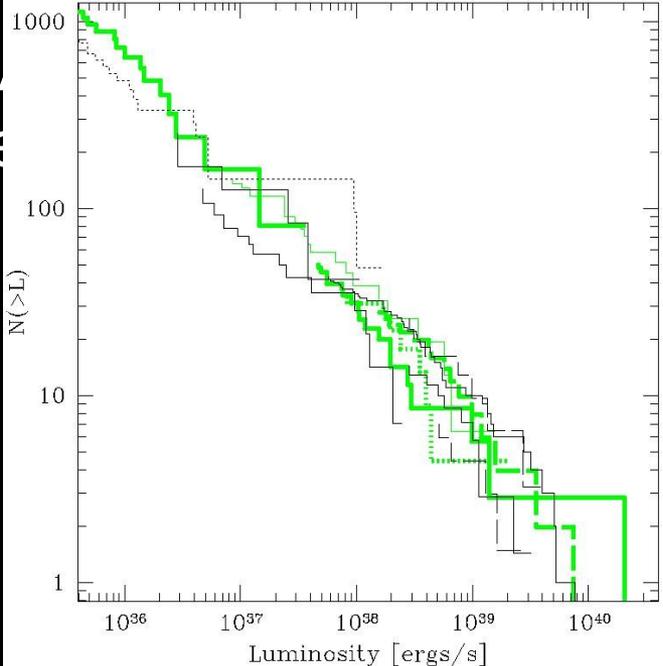

In collaboration with:

K. Gazeas, V. Antoniou, P. Sell, D. Pooley, J. Nantais, V. Kalogera

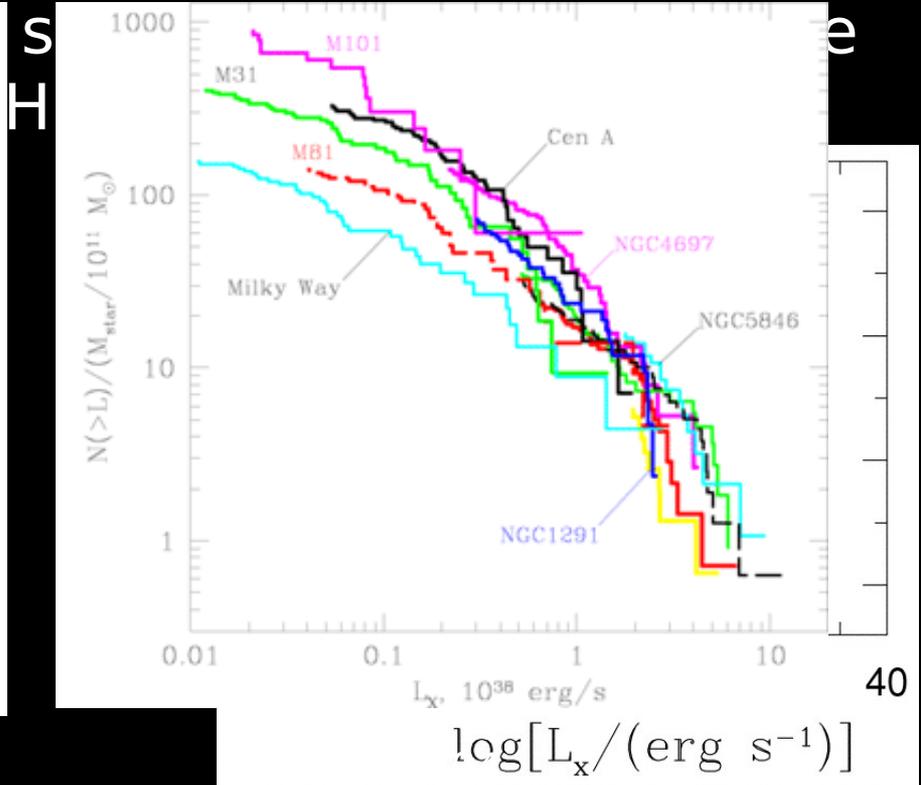

X-ray source populations

- There is evidence for a common XLF describing different XRB populations (e.g. Grimm et al 2002, Zezas & Fabbiano 2002; Kilgard et al. 2002; Colbert et al. 2004)

... but little is known about variations within each population

Grimm, Gilfanov, Sunyaev, 2002

M81: a case study

Extensively studied in virtually every waveband

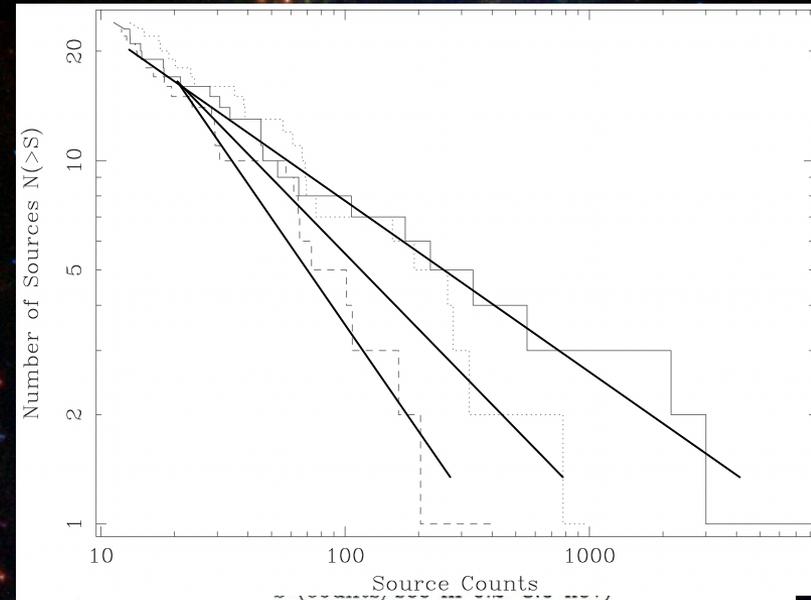

Nearby (3.6 Mpc) :

- Detect the bulk of active X-ray binaries
- Identify optical counterparts
- Resolve star-clusters, and measure structural parameters

X-rays : Deep exposures (PI D. Swartz) and monitoring campaign (PI D. Pooley)

Several populations of X-ray sources

Prime target to study star-formation *and* its relation to X-ray binary populations

Swartz et al 2000
Fernando et al 2000

Gordon et al 2004

Description of the Chandra observations

13 ACIS-S pointings (PI D. Pooley)

Cover $\sim 50\%$ of D25

Exposure : $\sim 10\text{-}15\text{ksec}$

Detection limit : $\sim 10^{37}\text{erg/s}$ in each pointing
($2 \times 10^{37}\text{ erg/s}$ @ 90% compl.)

$\sim 6 \times 10^{35}\text{ erg/s}$ in combined
exposure

($4 \times 10^{36}\text{ erg/s}$ @ 90% compl.)

Chandra observations : First results

50-60 sources in each pointing

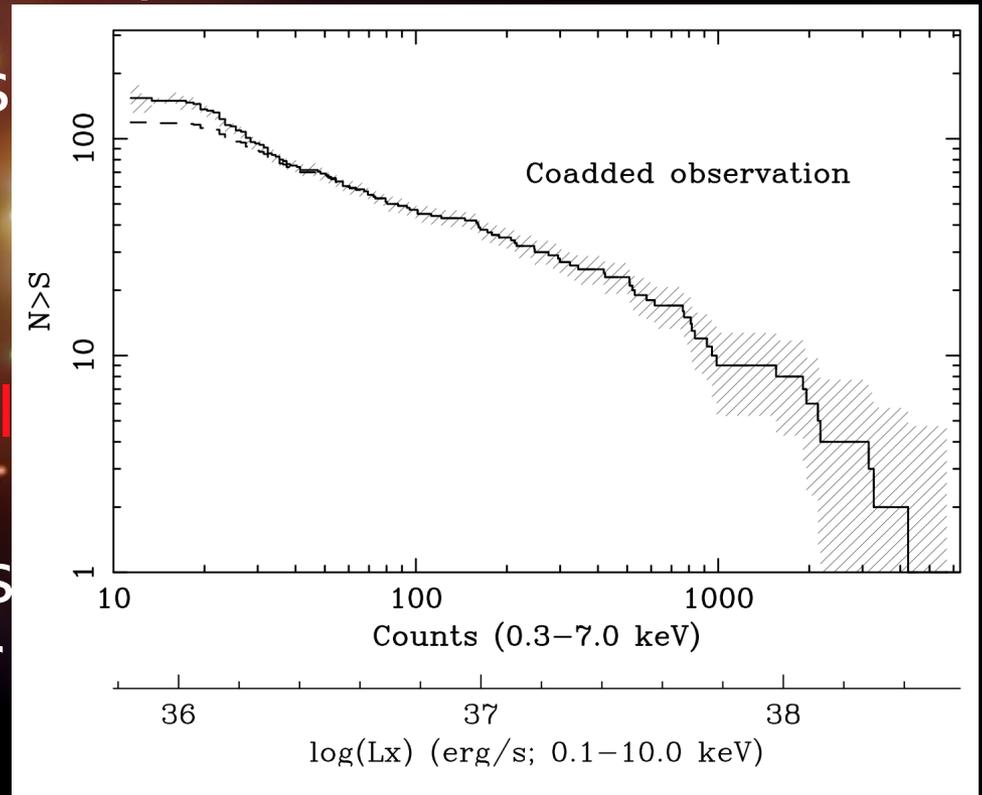

120 sources in coadded exposure

(~35 backgr. sources)

XLFs do not vary

(see poster by Paul Sell)

Consistent with results
on Antennae and other
star-forming galaxies
(Zezas et al 2007)

HST observations

HST-ACS BVI imaging of entire galaxy

Combination of P10540 (I-band; PI J. Huchra)
and P10584 (BV-bands; PI A. Zezas)

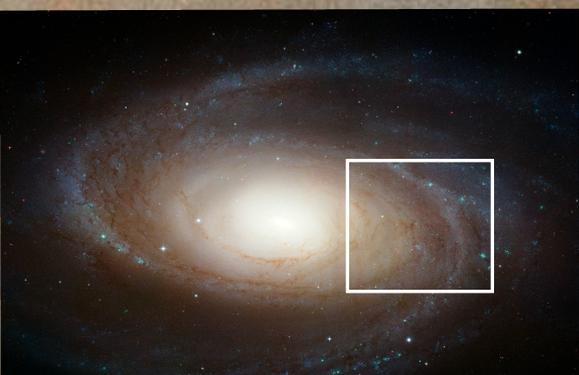

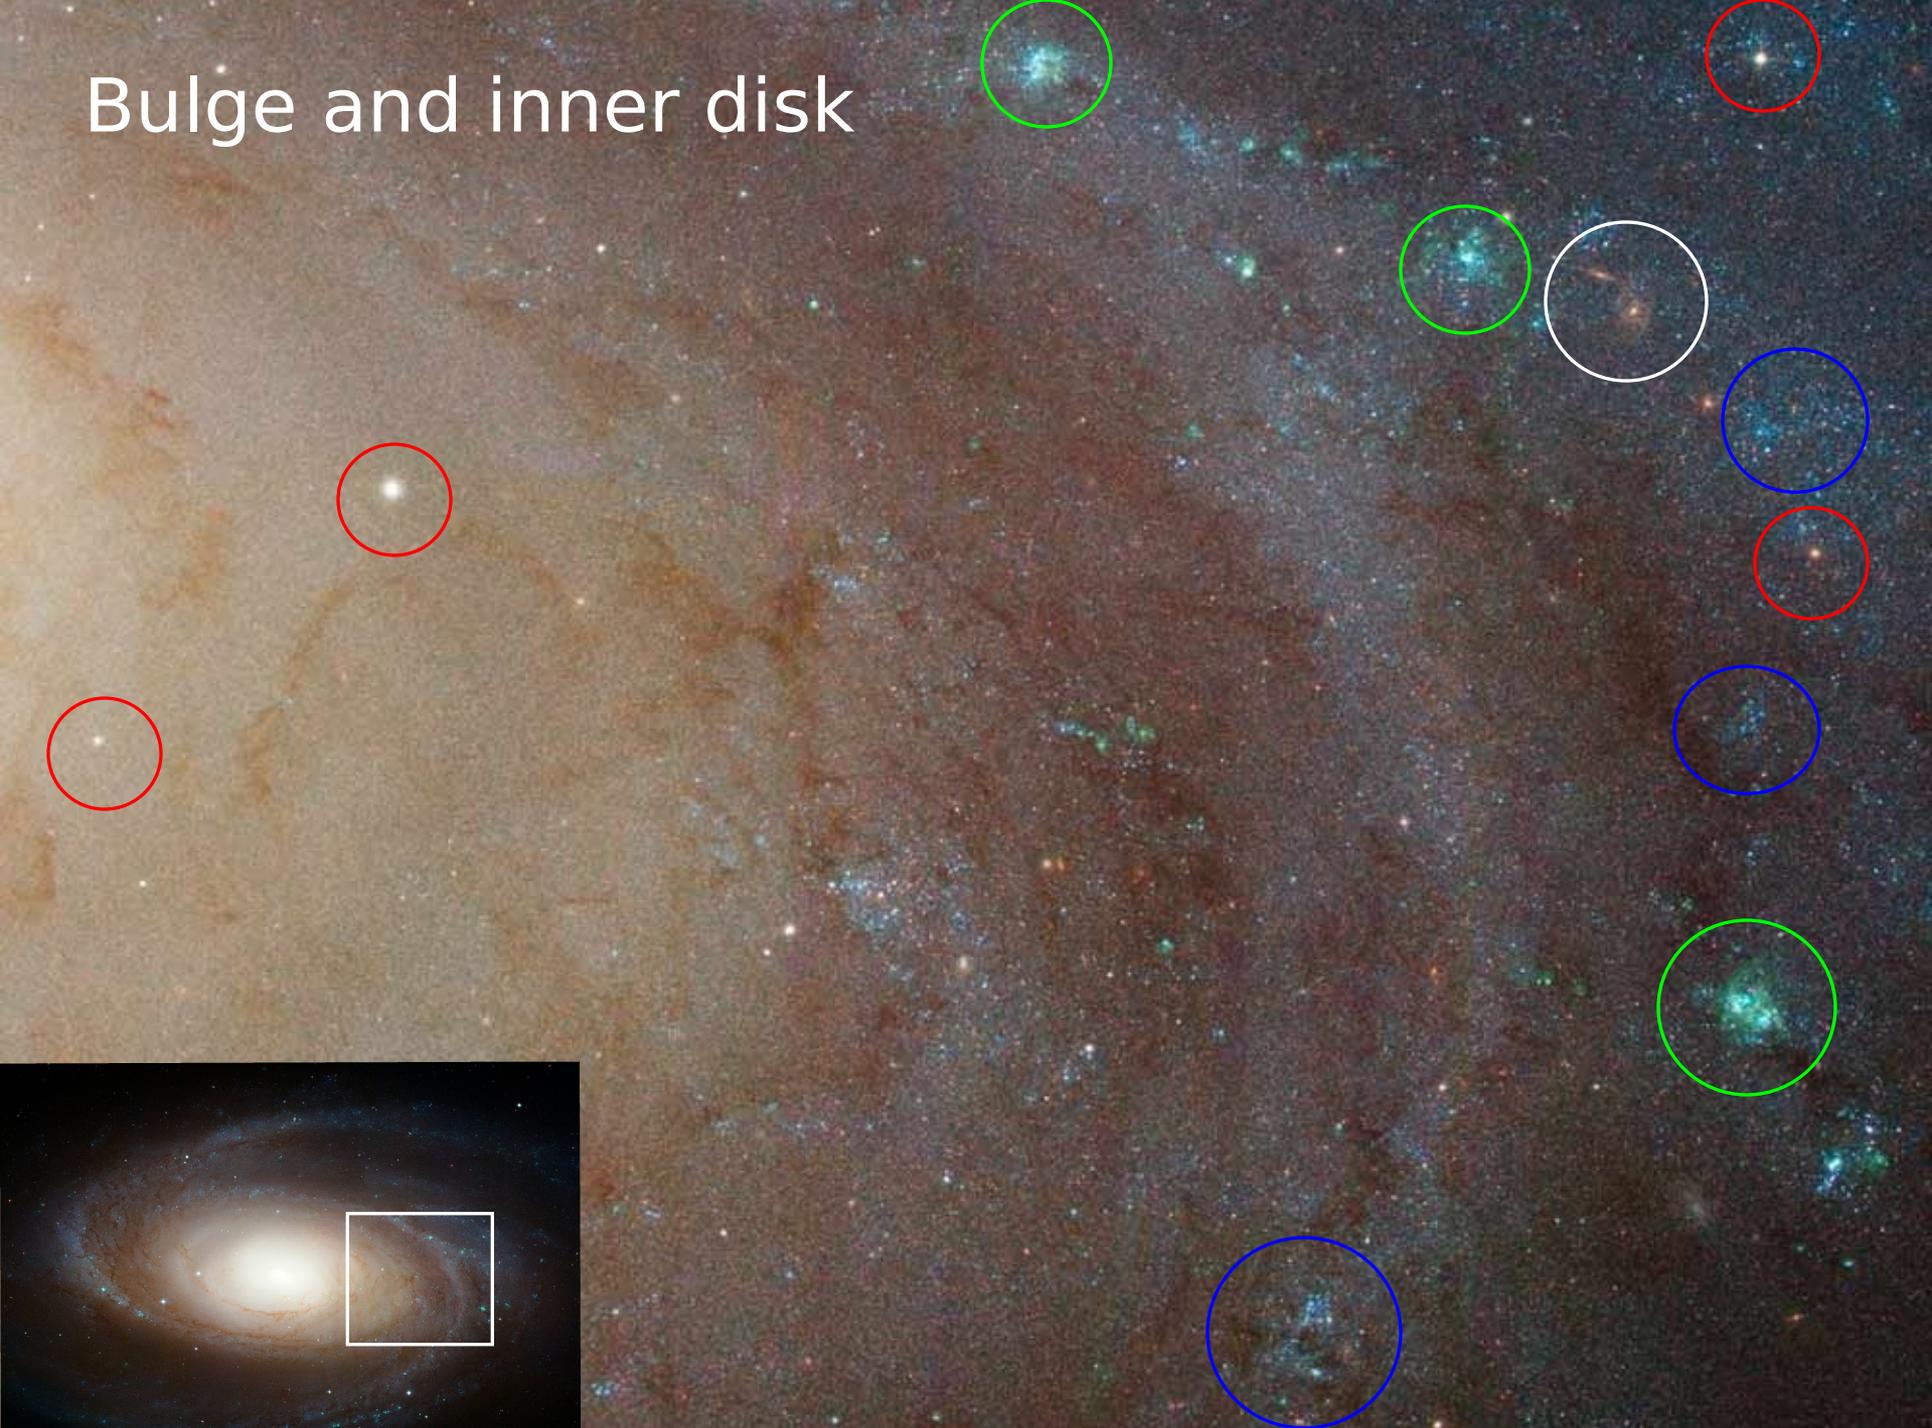

Total of 29 ACS fields (24+39 orbits)

B,V-band exposure : 1200 sec (~27 mag at
S/N=10)

I-band exposure : 1650 sec (~27 mag at
S/N=10)

Goal : Detect all star-clusters, and bulk of OB

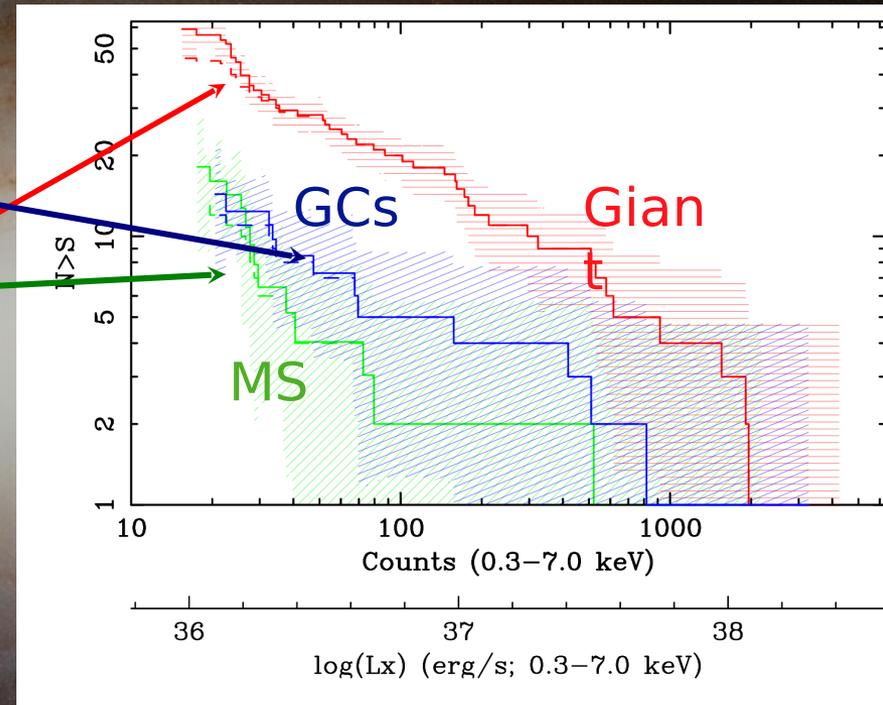

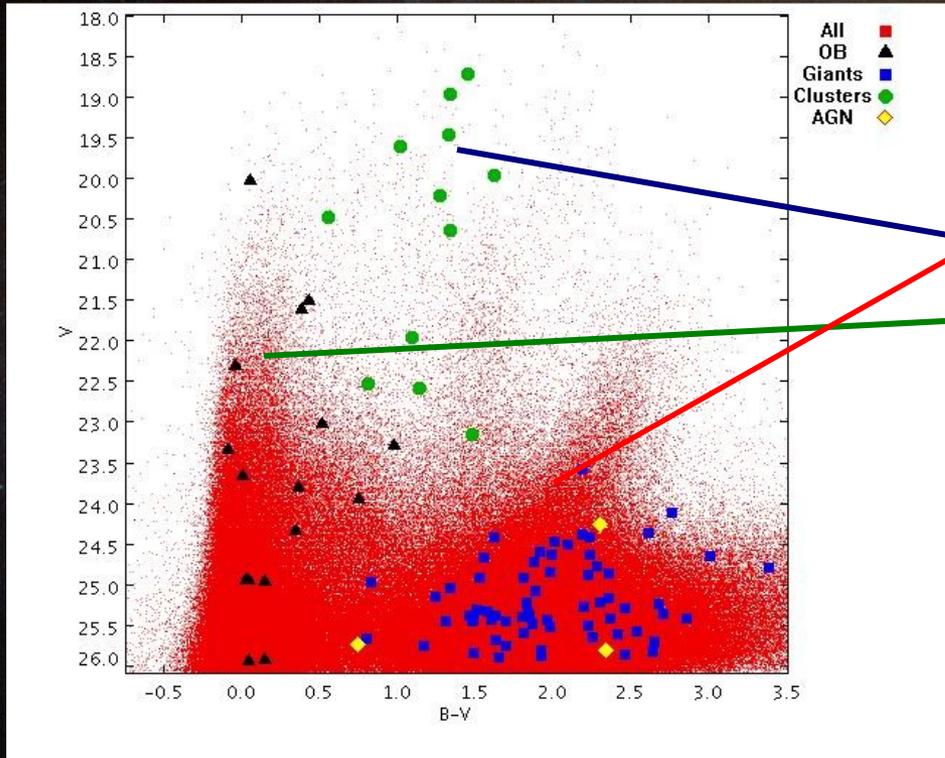

Bulge and inner disk

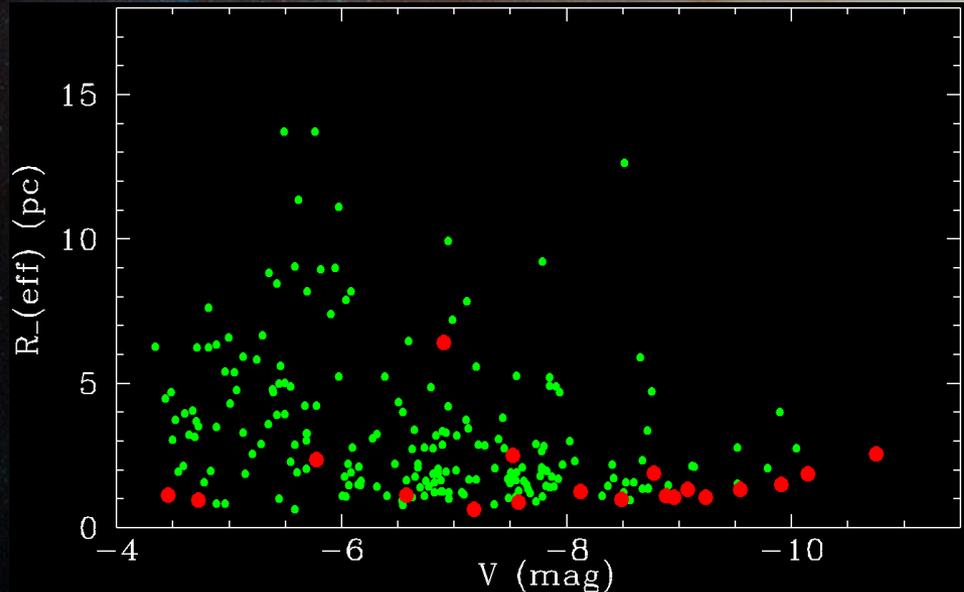

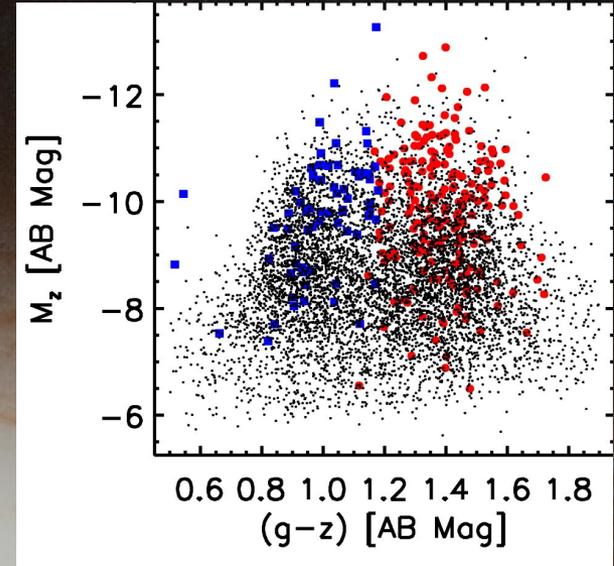

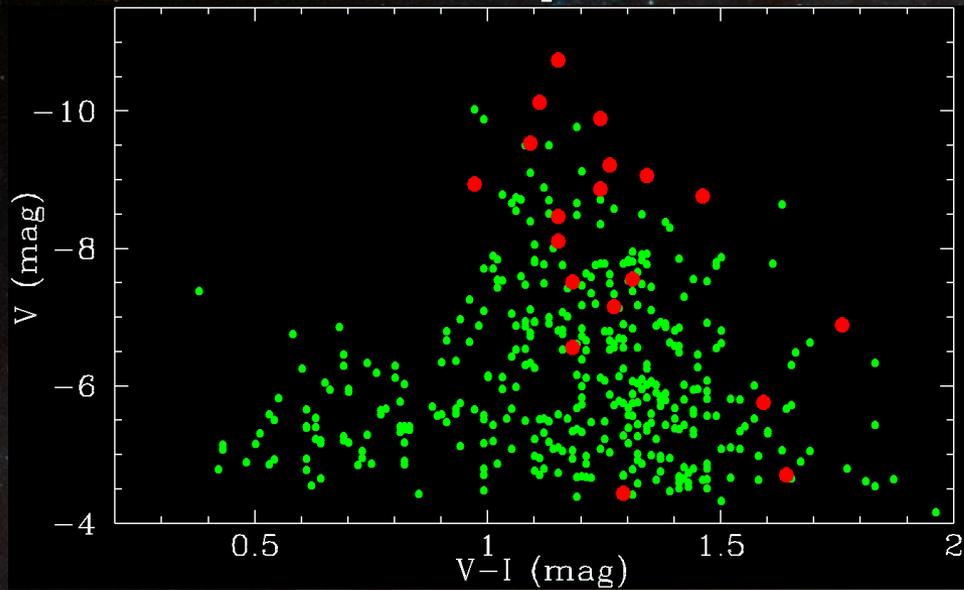

Comparison with Chandra

- Chandra-HST astrometric registration : $< 0.4''$
- Very high chance coincidence rate
- Cross-correlate with different source types
 - OB stars
 - Bright giants /supergiants

Comparison with Chandra

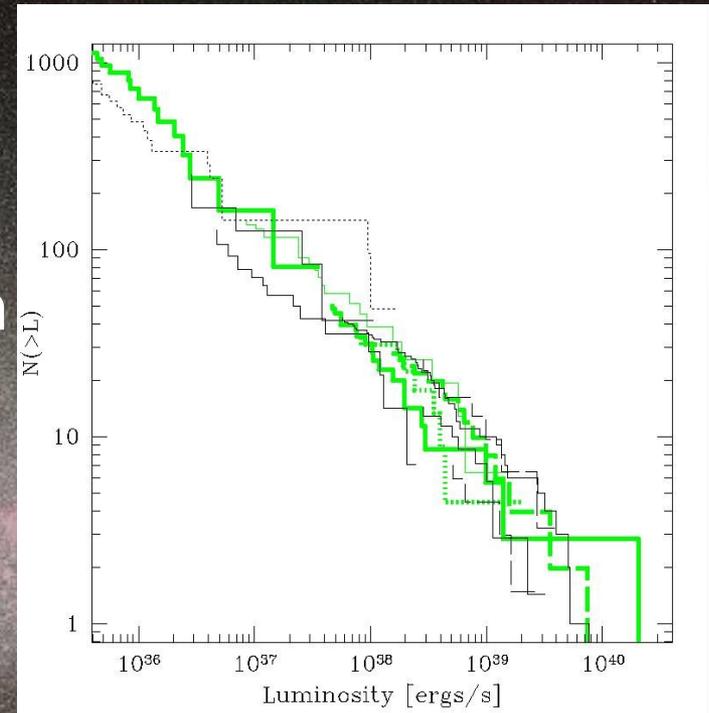

Comparison with Chandra

Star-forming galaxies

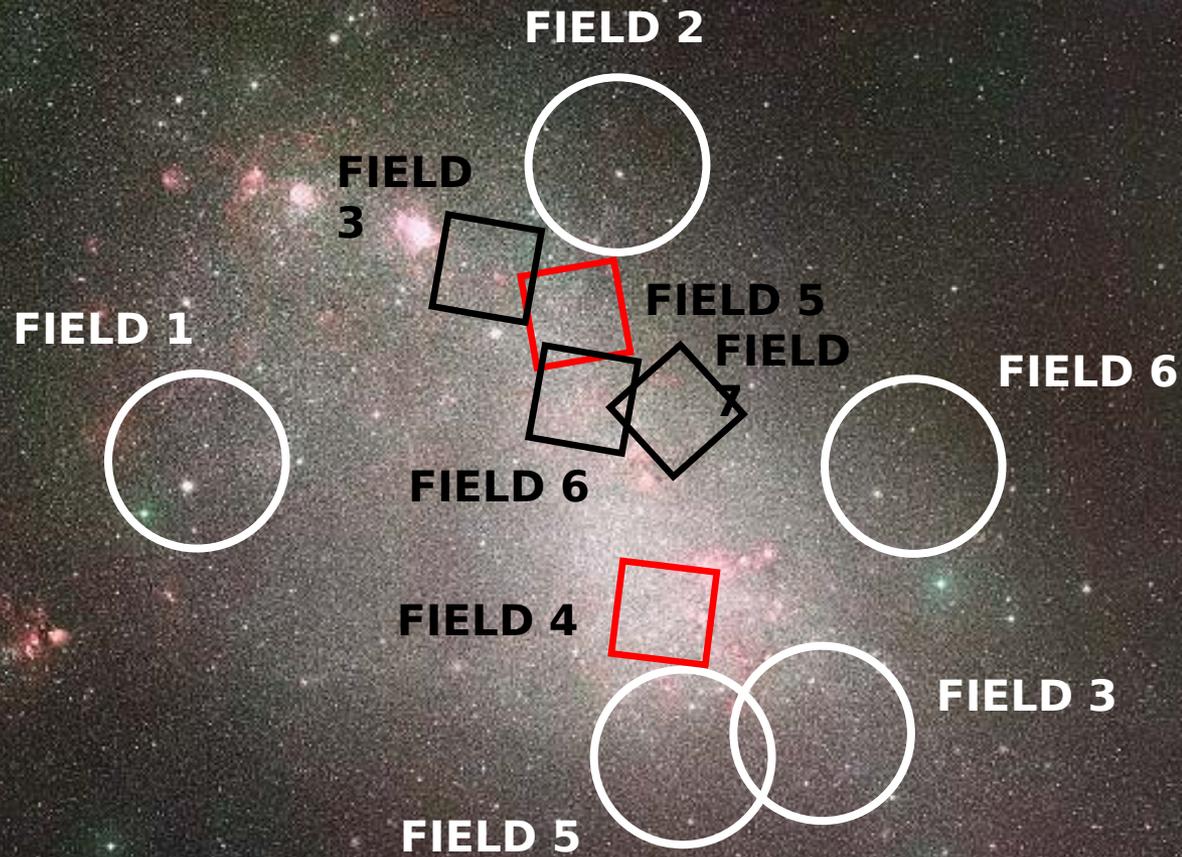

Common overall XLF, but

- Are there differences between populations ?
- What is the formation efficiency of X-ray binaries ?

Grimm, Gilfanov,
Sunyaev, 2002

The low-luminosity end: SMC

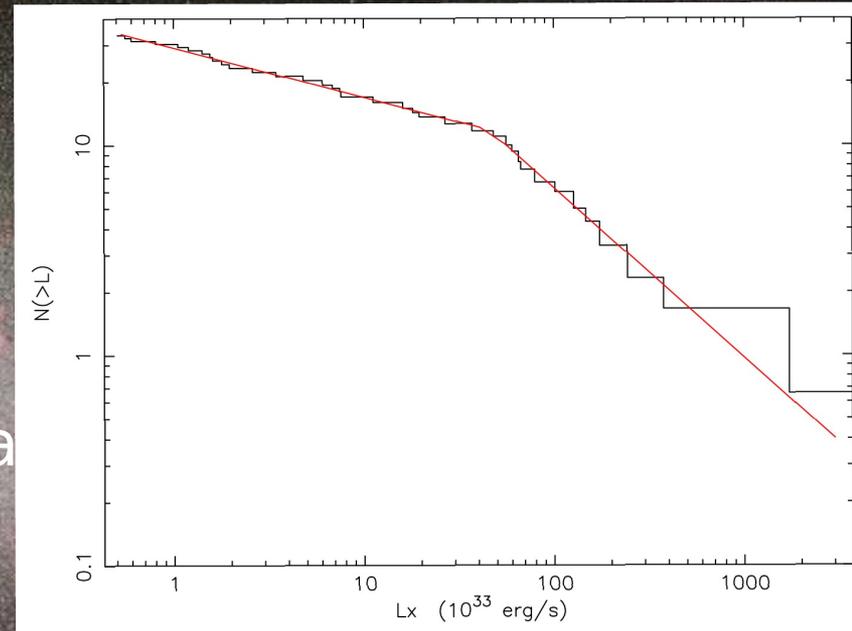

The low-luminosity end: SMC

The luminosity function:

Flat slope : $\alpha \sim 0.35$

Indication for break

consistent with accretion in a
inhomogeneous environment
and the onset of the propeller
effect.

Zevas et al, in prep.

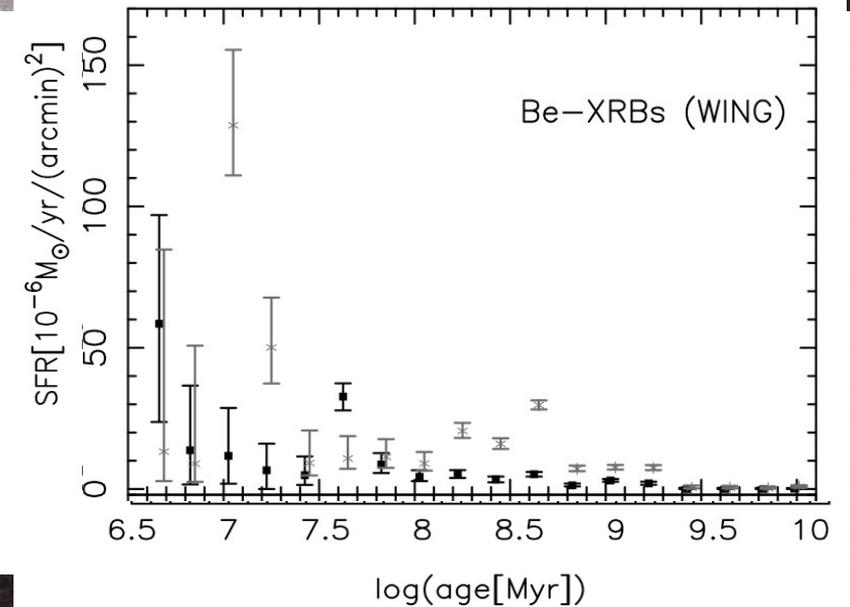

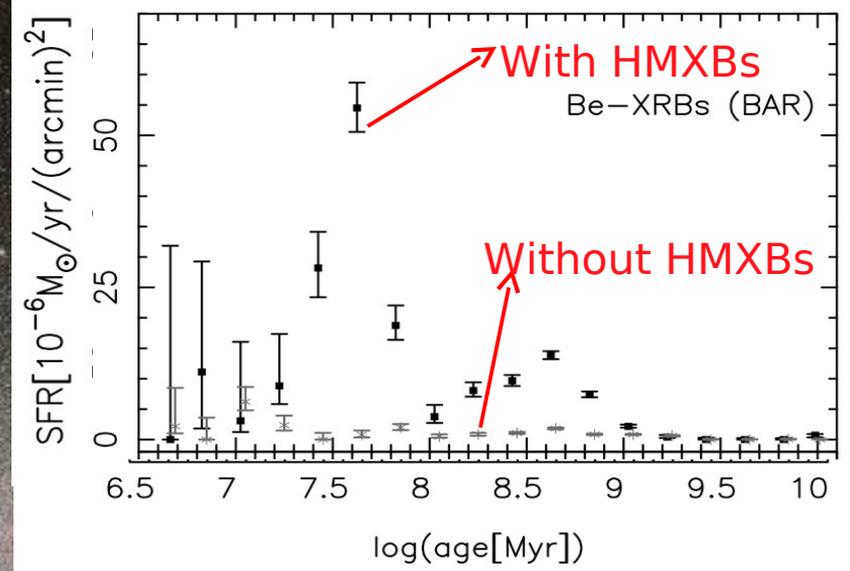

Relation with star-formation

Enhanced formation of X-ray binaries in the 30-70 Myr range.

Consistent with peak in Be-star phenomenon at these ages

Explains large number of XRBs in the SMC

Evidence for small kicks (c.f. van den Heuvel et al. 2000; Coe 2005)

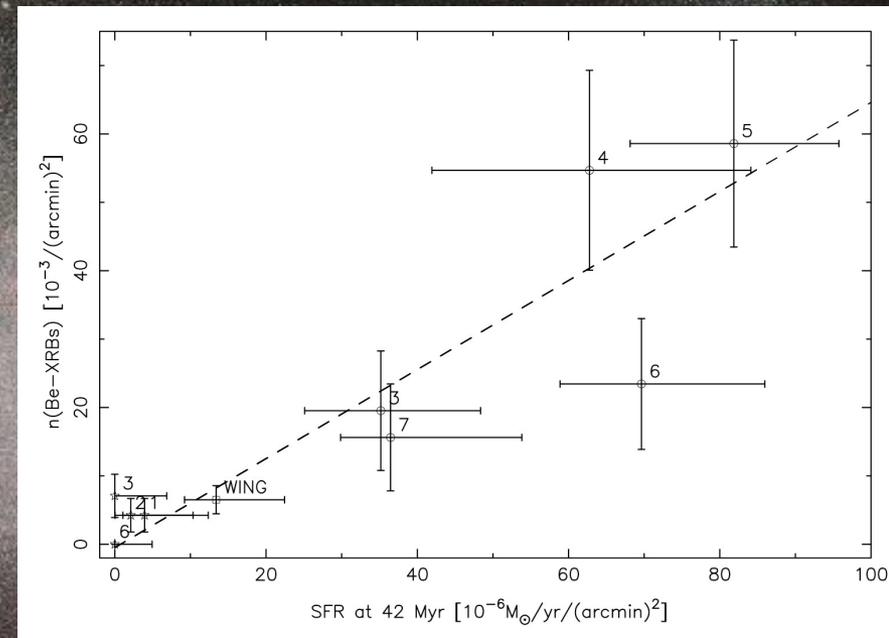

Relation with star-formation

Relation between Be-XRBs and SFR of **parent** population:

$$(1.6 \pm 0.6) \times 10^{-3} \text{ XRBs } / (M_{\odot} / \text{yr})$$

Extend relation based on studies of more distant galaxies to much lower luminosities.

Antoniou et al subm.

Summary

- Monitoring observations show that XLFs do not vary
- Multi-wavelength associations very useful for classifying X-ray sources and dissecting overall population.
- GC populations in M81 are consistent with ET galaxy GCs
- Strong dependence of HMXB populations on age.
- Need : systematic observations of nearby galaxies (e.g. XSINGs)
 - multiwavelength coverage
- Comparison with predictions from X-ray binary

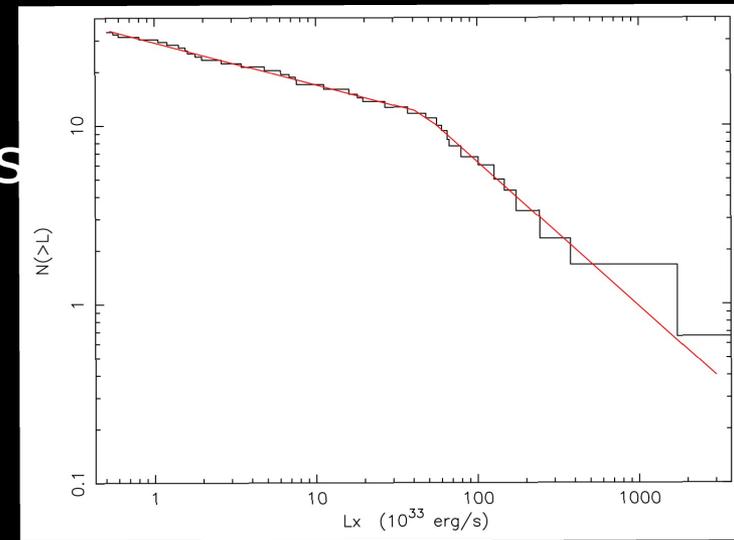

What comes next ...

Current studies require significant investment of Chandra time (100s ksec per object)

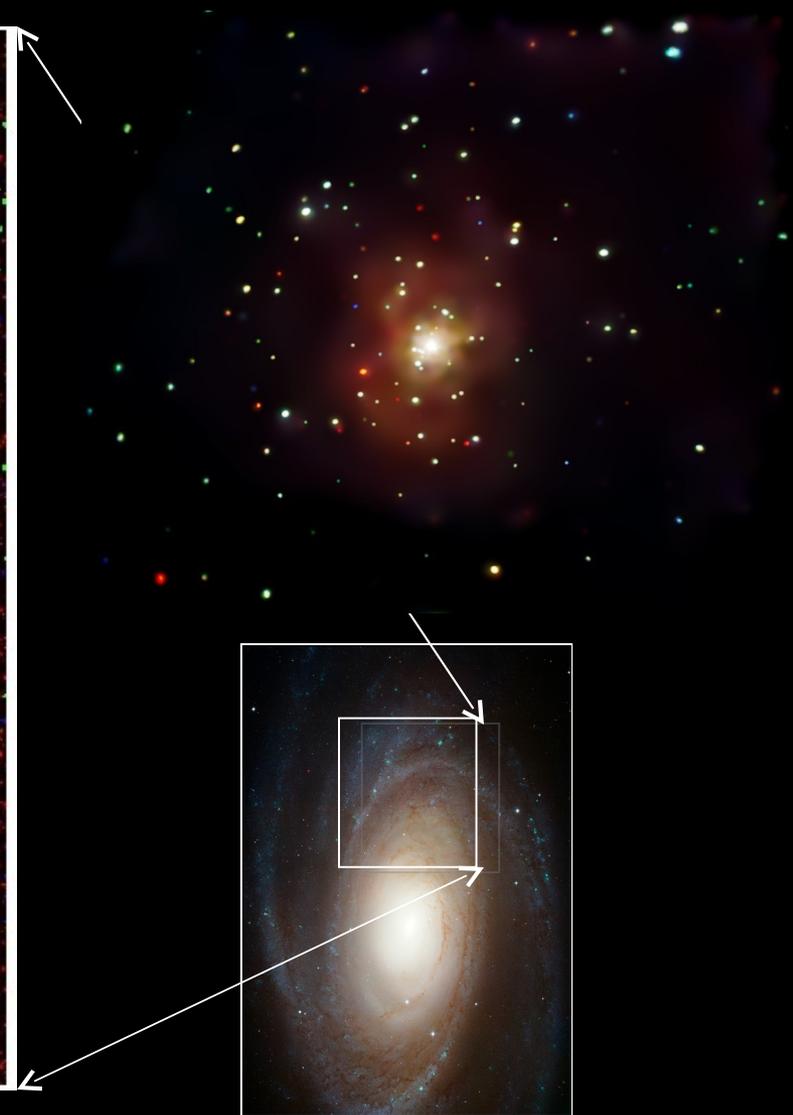

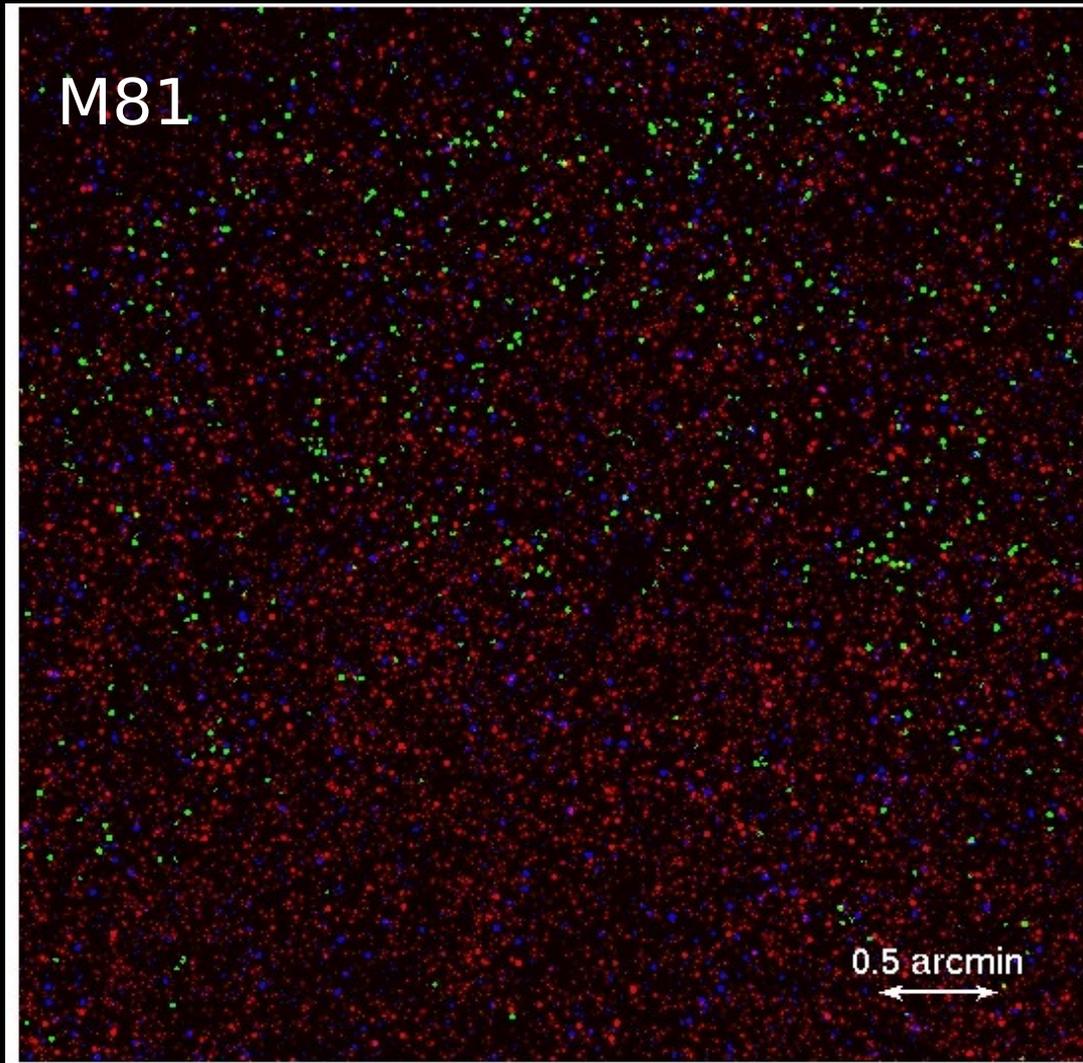

... and still cannot address the spectral/timing properties of the majority of objects

IXO will be very important for such studies in nearby galaxies

- accretion physics in low luminos
- detailed studies of relatively isolated sources (incl ULXs)

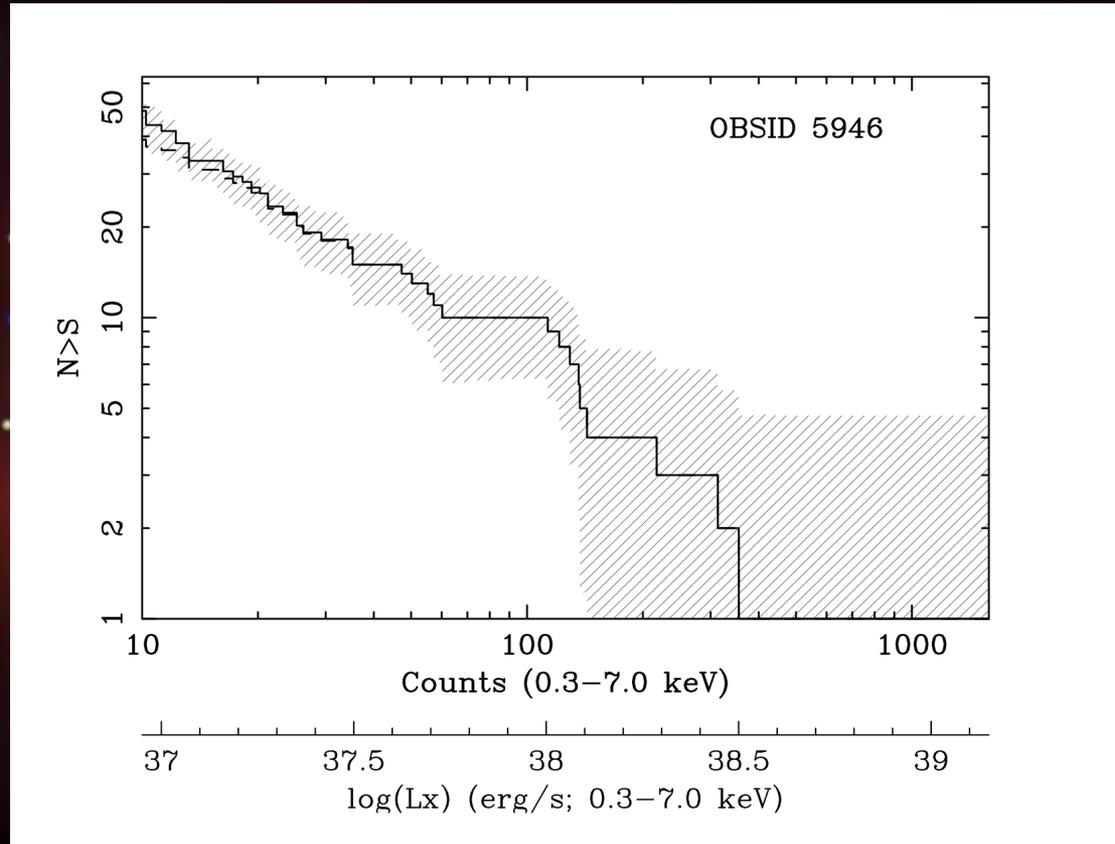

What comes next ...

100 ksec Gen-X simulation : Detection limit $\sim 10^{34}$ erg/s

Chandra observations : First results

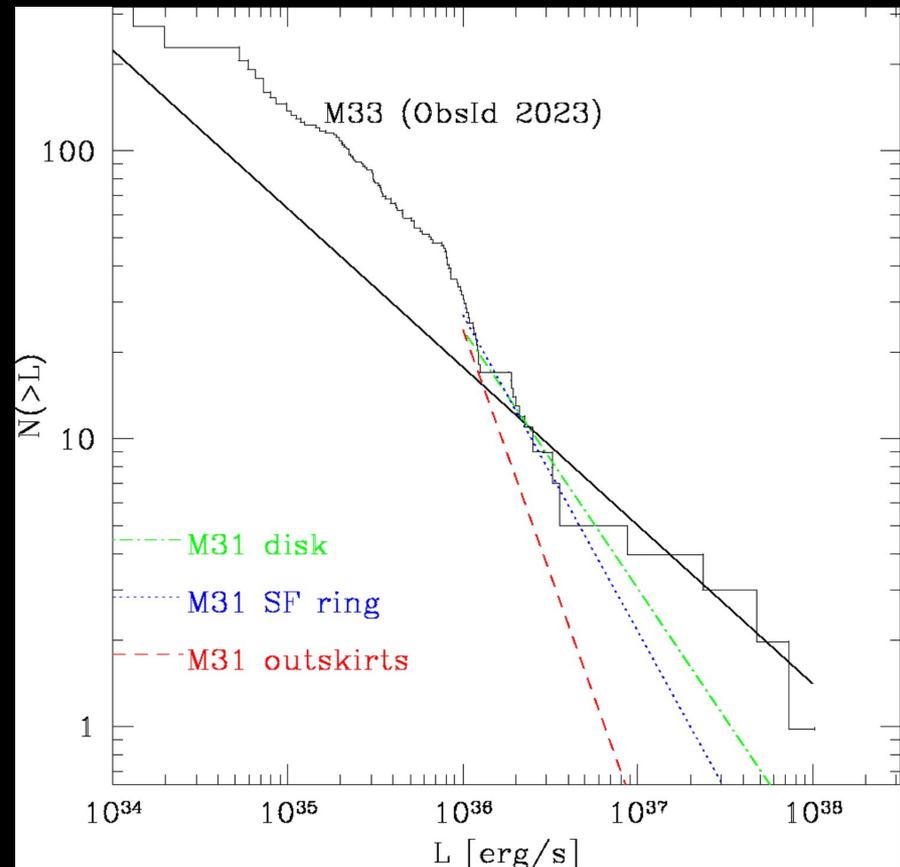

XLFs do **not** vary

Consistent with results from the Antennae and other star-forming galaxies

Spiral galaxies

There is strong evidence for different populations in star-forming galaxies (arms, bulge, inter-arm regions)

Grimm et al 2006

However, little is known about the properties of those X-ray sources.

Extragalactic X-ray source populations

Advantages:

- Often better distance determinations
- Less affected by obscuration
- Can study large samples of diverse types of sources and their connection to their parent stellar populations

Focus:

High Mass X-ray binaries (spiral, star-forming galaxies)
