total energy = 10<sup>61</sup> erg

bubbles stay intact for long times

Wise et al. 2007

#### **Evidence for turbulence in clusters**

- metal profiles in clusters (e.g. Simionescu et al. 2008, Rebusco et al. 2006)
- lack of resonant scattering in 6.7 keV Fe line in Perseus (Churazov et al. 2004)
- Faraday rotation maps (e.g. Enßlin & Vogt 2003)
- non-thermal emission in clusters (e.g. Brunetti & Lazarian 2007)

# Faraday rotation

# **Faraday rotation**

Maximum likelihood power spectrum estimate using 3-d window, assuming statistical isotropy, div B = 0.

Enßlin & Vogt (2003), Vogt & Enßlin (2005)

# **Faraday rotation**

### cluster cool core

Hydro turbulence induced by buoyantly raising radio bubbles has the right strength & length-scale to drive observed magnetic turbulence (Enßlin & Vogt 2006)

### **M87**

Simionescu, Böhringer, Brüggen, Finoguenov (2006)

### **Metals in Perseus**

Rebusco et al., MNRAS 359, 1041 (2005)

### **Cooling time**

**Perseus cluster** 

The ICM may be turbulent

**Rayleigh-Taylor unstable bubbles induce turbulence** 

AGN-blown bubbles stay intact for long times

**Rayleight-Taylor instabilities cannot be simulated for Re > 10000** 

### Main Question:

How much turbulence do bubbles produce in the ICM and what does this turbulence do to the bubbles?

# **Rayleigh Taylor Instability**

# **Rayleigh Taylor Instability**

 $h_b = \alpha_b A_o g t^2$ 

# **Dimonte & Tipton Â06 Turbulence Model**

based on buoyancy-drag models for RT and RM instabilities: self-similar, conserves energy, preserves Galilean invariance, works with shocks

**K** = Turbulent KE , L= Turbulent Length Scale

$$\begin{split} \frac{\partial \bar{\rho}K}{\partial t} + \frac{\partial \bar{\rho}K\tilde{u}_{j}}{\partial x_{j}} &= \frac{\partial}{\partial x_{j}} \left( \frac{\mu_{t}}{N_{K}} \frac{\partial K}{\partial x_{j}} \right) - R_{i,j} \frac{\partial \tilde{u}_{i}}{\partial x_{j}} + S_{K} \\ & \text{turb. diffusion} \quad \text{work associated with source term with turbulent stress} \quad \text{RM and RT contributions} \\ \frac{\partial \bar{\rho}L}{\partial t} + \frac{\partial \bar{\rho}L\tilde{u}_{j}}{\partial x_{j}} &= \frac{\partial}{\partial x_{j}} \left( \frac{\mu_{t}}{N_{L}} \frac{\partial L}{\partial x_{j}} \right) + \bar{\rho}V + C_{C}\bar{\rho}L \frac{\partial \tilde{u}_{i}}{\partial x_{i}}, \\ & \text{turb. diffusion} \quad \underset{\text{through turb. motion}}{\text{growth of eddies}} \quad \underset{\text{through motion in mean flow}}{\text{growth of eddies}} \\ S_{K} &= \bar{\rho}V \left[ C_{B}A_{i}g_{i} - C_{D} \frac{V^{2}}{2} \right], \qquad \mu_{T} = C_{\mu}\bar{\rho}LV, \qquad V \equiv \sqrt{2K} \\ & \text{buoyancy} \qquad \text{drag} \qquad \underset{\text{turb. viscosity}}{\text{turb. viscosity}} \quad \underset{\text{turb. velocity}}{\text{turb. velocity}} \end{split}$$

### **Modified fluid equations**

leading order in expansion around mean velocity: mean quantities are modified by presence of

- 1. Reynolds stress R
- 2. Turbulent viscosity, mu
- 3. Source term  $S_{\kappa}$

$$\frac{\partial \rho u_i}{\partial t} + \frac{\partial \rho u_i u_j}{\partial x_j} = -\frac{\partial P}{\partial x_i} - \frac{\partial R_{i,j}}{\partial x_j}$$

$$\frac{\partial \rho E}{\partial t} + \frac{\partial \rho E u_j}{\partial x_j} = \frac{\partial}{\partial x_j} \left( \frac{\mu_t}{N_E} \frac{\partial E}{\partial x_j} \right) - \frac{\partial P u_j}{\partial x_j} - S_K$$

#### **Rayleigh-Taylor Shock Tube Test from DT06**

solid: simulation dashed: analytic

$$L(x,t) = L(t,0)[1 - x^2/h(t)^2]^{1/2}$$
  

$$K(x,t) = K(t,0)[1 - x^2/h(t)^2]$$
  

$$h(t) = \alpha A(0)t^2$$
  

$$L(t,0) = h(t)/2$$
  

$$K(t,0) = (dh/dt)^2/2$$

K, L and mu increase as t<sup>2</sup> -> rapid mixing between materials

## **Simulation setup**

- numerical implementation in FLASH3.0 framework
- Equations for K and L are evolved explicitly (with addl. timestep constraint)
- momentum and energy equation modified by source term, Reynolds tensor and turbulent viscosity
- initially hydrostatic cluster, static gravity
- 5 levels of refinement (3-6), 1024^3 eff. res., (650 kpc)^3 box
- bubbles are produced by
  (a) evacuation in pressure equilibrium
  (b) injection of energy into spherical regions (Sedov-type), r = 10 kpc
- metal injection proportional to light distribution
- metal fraction in each cell represented by mass scalar
- radiative cooling by thermal bremsstrahlung

with subgrid

T increase not due to turbulent dissipation but mixing

red: with subgrid blue: w/o subgrid green: no bubbles In pure hydro run, bubbles fragment after single pressure scale height.

Dominant unstable modes are set by grid resolution.

Subgrid models captures growth of modes that the grid cannot resolve.

It smears out the interface between bubble and ambient medium and keeps the bubbles intact.

Metal transport is enhanced.

Dependence on resolution

$$\lambda_{\rm max} = 4\pi (\nu^2 A/g)^{1/3}$$

 $\mathrm{Re}\sim 2000-5000$ 

 $\nu \sim dv/{\rm Re} \sim 3\,{\rm km\,s^{-1}kpc}$  $\lambda_{\rm max} \sim 2\,{\rm kpc}$

# No Turbulence No Shocks

# **Turbulence No Shocks**

Turbulence + Shocks

### Conclusions

• We tried a K-L subgrid model to study the RT and RM driven turbulence in galaxy clusters.

• RT and RM instabilities that drive the evolution of bubbles result in motions on many scales that are far below the resolution limit of current simulations. The superposition of unstable modes smears out the interface between bubbles and ambient medium and prevents break-up of bubbles. This mixing explains the appearance of X-ray cavities. Subgrid models are needed to capture this physics.

• Subgrid turbulence enhances metal transport in clusters; typical turbulent diffusivity: 500 km/s kpc - in line with observations of metal profiles in Perseus

• Turbulent energy is about 1% of total energy in bubbles available to heat the cluster. Subgrid turbulence plays no role in heating cool cores.

• Turbulent motions can be probed with Con-X.

• In simulations where RT and RM instabilities occur, proper treatment of subgrid physics can be essential!
